Workshop – Prague October 2018

CrypTool – A Wide-Spread and Free Program to Help Raising Crypto Awareness

Prof. Bernhard Esslinger

Introduction

During this workshop you will learn how to apply CrypTool 2 (CT2) to encrypt and decrypt texts using different ciphers. We will briefly present some attacks on the ciphers as well as a basic introduction to password (in-)security. You will touch the understanding of the importance of some cryptographic concepts like randomness. This exercise material can also be used as an instruction manual for CT2.

Structure of this workshop

1. Symmetric Cryptography ........................................................................................................... 2
   a. Classic Cipher (Caesar) ........................................................................................................... 2
   b. Modern Cipher (AES) ............................................................................................................ 5
2. Asymmetric Cryptography (RSA Cipher) ..................................................................................... 9
3. Password Security ....................................................................................................................... 15
Appendix 1: Introduction to the CrypTool 2 Application ................................................................. 17
Appendix 2: Task Overview ............................................................................................................. 30
Appendix 3: Links and References / Literature ............................................................................. 31

The first chapter Symmetric Cryptography shows how to work with ciphers, i.e. encrypting and decrypting texts. First (ca. 12 min), we use a Caesar cipher, which was used centuries ago by the Romans. Then (ca 10 min), we encrypt a text using a modern symmetric cipher (Advanced Encryption Standard AES) and show how to perform a brute-force attack. The second chapter (ca. 11 min) shows how to use CT2 to encrypt a text using the RSA cipher. Furthermore, we show how to attack the RSA cipher by factorization (general approach) and in the faulty case when RSA used shared prime factors. The third chapter (ca. 7 min) introduces the (in-)security of passwords and applies a dictionary attack.

There are 3 appendixes: The first (and extensive) appendix introduces the usage of the CrypTool 2 application. Due to time restrictions, this chapter is intended for reading at home as a recapitulation of the usage of CT2. The second appendix contains an overview of all tasks of the workshop. The third appendix offers links, references, and literature.
1. Symmetric Cryptography

a. Classic Cipher (Caesar)

CrypTool 2 (CT2) contains various classic ciphers. First, we use the Caesar cipher, which is one of the easiest substitution ciphers.

Task 1: Decrypt the following text using the Caesar cipher built in CT2

Va pelcgbtencul, n Pnrfne pvcure, nyfb xabja nf Pnrfne'f pvcure, gur fuvsg pvcure, Pnrfne'f pbqr be Pnrfne fuvg, vf bar bs gur fuzcyrfg naq zbfg jvqryl xabja rapelcgvba grpuavdhfr. Vg vf n qler bs fhofgvghgva pvcure va jvpu rpnu yrgrq va gur cynvagrkg vf ercynprq ol n yrgrq fbzr svkrg ahzore bs cbfgvbaf qbja gur nycunorg. Sbe rknzcyr, jvgu n yrsg fuvsg bs 3, Q jhhyq or ercynprq ol N, R jhhyq orpbzr O, naq fb ba. Gur zrughq vf anzrq nsgre Whyvhf Pnrfne, jub hfrq vg va uvf cevingr pbeerfcbaqrapr.

Key: 13

Hint 1: Open the template “Caesar Cipher” in CT2 (or use the Wizard).
Hint 2: To copy the ciphertext above, mark it in this pdf with the mouse and press “Control key + C”. Then in CT2, enter the text by pasting it (pressing “Control key + V”) into the text input component called “Plaintext”. Change the Caesar parameter “Action” from “Encrypt” to “Decrypt”, and adjust the given key to 13. In order to start the template, click on the “Play” button.

Task 2: Encrypt the following text using the Caesar cipher built in CT2

Gaius Julius Caesar known by his cognomen Julius Caesar was a Roman politician and military general who played a critical role in the events that led to the demise of the Roman Republic and the rise of the Roman Empire. He is also known as an author of Latin prose.

Key: 10
**Task 3:** Break the following text using the template “Caesar Analysis using character frequencies”

Pu jyfwavnyhwof, h jpwoly pz hu hsnvypat mvy wlymvyspun luujfwavpu vy kljyfwapvu -- h zlyplz vm dlss-klmulpk zaiwz aoha jhu il mvyszvdik hz h wyvylkbyl. Hu hsalyhapcl, slzz jvttvu alyt pz luujpwoyltua. Av luujpwoy vy luujkvl pz av jvuclyapummvymvpv puv jpwoly vy jvkl. Pu jvttvu wyhuylj, "jpwoly" pz zfuvytfvblz dpao "jvkl," hz aolf hyl ivao h zla vm zaiwz aoha luujfwa h tlzhhnl; ovdclcy, aol jvujlwaz hyl kpzaupja pu jyfwavnyhwof, lzwijphssf jshzzpjhs jyfwavnyhwof.

Hint: After entering the ciphertext from above, click on the “Play” button.
b. Modern Cipher (AES)

CrypTool 2 (CT2) contains different modern ciphers. We will have a closer look at the **Advanced Encryption Standard (AES)** cipher, which is the current standard for modern block ciphers.

Open the according templates in CT2 – again by using the template filter and entering the string “AES”.

**Task 4:** Decrypt the following text using the AES cipher built in CT2 (ciphertext data is hex encoded)

```
0D 96 CF F8 7A 16 54 62 61 07 2D F3 E2 60 FD F9 9A 2C 05 FF 44 D5 B3 13 B8 28 C9 66 48 EC C8

A5 E4 9F 65 C9 06 FD 5D 65 1B 52 17 19 A4 D2 EE 12 9D 10 FF 47 85 C3
```

**Key:** FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF

**Hint:** The cipher used was AES-128. Set the key in the settings of the “Key Searcher” to FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF. One hex character corresponds to 4 bit; a 128 bit key can be described by 32 hex chars (32*4=128). Here, the last 6 hex chars are asterisks, so 24 bit are unknown.

**Task 6a:** Same task as before, but less known key bits

Try using patterns with more additional asterisks (*) to get a feeling of search time if you know less bits of the key:

```
FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-FF-F*--**--**--
```

This means, we know 4 bits less than before (first we knew 128-24=104 bit; now, 7*4=28 bits are unknown, so we know 100 bit of the AES key). For all unknown bits the KeySearcher component in CT2 processes an exhaustive search (brute-force attack). 4 more unknown bits mean that we can expect that the brute-force attack needs $2^4=16$ times the time needed before. Each unknown bit doubles the time needed. On my laptop task 6 needed 35 seconds; task 6a needed 9 minutes.
Remark: **Block modes of modern symmetric ciphers**

There are two big families of modern symmetric ciphers: block and stream ciphers. Stream ciphers work on single bytes, block cipher work on blocks of $n$ bytes, where $n$ usually is 64, 128, or 256.

AES-128 is a block cipher with a block length of 128 bits (= 16 byte) and a key length of 128 bit. NIST defined three AES standards: AES-128, AES-192, and AES-256, each with a block size of 128 bit, but three different key lengths: 128, 192, and 256 bit.

If you encrypt messages longer than one block, you have to decide how you make sure, that all blocks are full and how to build consecutive blocks. To do so, there are different standards – the one recommended today in most cases is the GCM mode. The following 2 templates show how block modes work and what can happen if you choose a wrong one.
2. Asymmetric Cryptography (RSA Cipher)

CrypTool 2 (CT2) contains different asymmetric methods. The RSA Cipher is named after their inventors Rivest, Shamir, and Adleman.

**Task 7:** Decrypt the following text using the RSA cipher built in CT2

```
88 9D D8 2A 7A 14 8C 06 79 BA AC BB B5 1E C1 4A AF 84 B5 FE A5 0B 1D C3 C6 D9 8D 4C 01 74

Hint: Open the template “RSA Decryption” in CT2 (or use the Wizard). You need the parameters of the private key to do the decryption.

**Task 8:** Encrypt the following text using the RSA cipher built in CT2

The idea of an asymmetric public-private key cryptosystem is attributed to Whitfield Diffie and Martin Hellman, who published this concept in 1976.

Key: Same as in Task 7. Don’t confuse e and d.

Hint: Open the template “RSA Encryption”.

---

CRYPTOOL 2 TEAM – PRAGUE 2018
Task 9: Break the following ciphertext by factorizing the small N (59 decimal chars, 195 bit)

```
65 13 D4 83 A9 FF AD 6F E4 35 F1 B0 98 F9 31 D8 16 8D C3 B6 20 47 E7 D8 05 18 B0 52 EB 1F 3E
CF 0C EA C3 6C 8E A3 63 B0 B6 9A 09 4C 55 4F AA 62 E5 00 52 17 F1 BB 1C 43 AC 21 02 98 BE 1E
E0 E4 EA 18 C1 4B D6 4C 18 BC 2F AA 06 41 2A 10 D4 70 B5 2E 4C 58 E4 E1 BE 49 8D E0 B3 0C 26
9C 78 F6 47 67 F9 06 B4 FE EF 9C AB AE 07 89 2F 47 17 F3 BA D8 CE 85 41 ED 80 15 14 6D 6E
05 87 77 13 62 DB 1E 25 A7 DD 9D 3B D4 99 AD 71 95 7E 2D 77 32 04 1D 68 13 03
```

Key:

\[ N = 47492644722910949726131741244721188759641455368884720418747 \]

\[ e = 11 \]

Hint 1: As you now only know the parameters of the public key \((e, N)\), you additionally need to do something to get the private key too (the private key is needed for decryption).

So first, use the template “Factorization with Quadratic Sieve (QS)” to factor \(N\) into \(p\) and \(q\).

Hint 2: Then, use the template “RSA_Decryption”. Here, enter the values for \(p\), \(q\), and the public exponent \(e\) in the component “RSA Key Generator”. Finally, enter the ciphertext and decrypt it by starting the template.
Remark 1:
The following dialog box from CT1 shows the length of the above $N$ in different number representations.

Remark 2:
The longest RSA module $N$ which was constructed securely and which was factorized yet, had a length of 768 bits (as far as known by public research and on conventional computers). Researchers think that NSA is able to factorize 1024 bit RSA keys.
**Task 10:** Now we consider a case where the RSA keys were not constructed securely. RSA can be broken easily if for the generation of two different RSA keys a common prime factor happened to be used. The following two RSA modules $N_1$ and $N_2$ (each ca. 2048 bit) share a common prime factor $(Q)$.

This sample shows how important good randomness is when generating keys. (And trust, if you let others generate keys for you.)

$$N_1 = 49141803551209330395504421973190597473237847949094050702331992002072658$$

```

Hint: Here, you need to download a template (cwm file) from the same website as where you downloaded this workshop material (pdf): “RSA Common Factor Attack.cwm”

First, open the provided template. Here, enter $N_1$ and $N_2$ to compute the greatest common divisor (gcd) $Q$ as well as the two other factors $P$ and $R$.

Then, open the template “RSA_Decryption” and enter the values $P$, $Q$, and $e$ into the “RSA Key Generator”. Finally, enter the ciphertext in the according text input component and decrypt it.
Remark: **Asymmetric keys and certificates**

When using RSA for encryption, the sender (here called Alice) has to use the public key of the recipient (Bob).

**Different keys used for encryption and decryption, each person has a different key pair.**

The association of a public key and an identity can be assured with a public key certificate.

The sender does not need any secret information, because the certificates are public and can be exchanged unencrypted. However, the private key must not leave its owner’s key store.

In real-world applications the public key is packed into a certificate, which “signs” this public key, adds the according email address, and also a validity period.

If an application, which you want to do the encryption (like an email client) states, that a communication partner’s “key isn’t valid”, this normally doesn’t mean that the key is wrong -- it wasn’t revoked. In most cases, today is just after the validity period stated in the certificate. So it should better tell you, that the used certificate isn’t valid any more, and that you need to ask your communication partner to send you a new certificate.
3. Password Security

CrypTool 2 (CT2) contains different hash functions and key derivation functions. To find them, go to the Startcenter and use the template list to search for appropriate templates. Modern password hashing uses key derivation functions like PBKDF2 (better than PKCS#5 1.x) – see https://en.wikipedia.org/wiki/Password_hashing or https://en.wikipedia.org/wiki/PBKDF2. In CT2 this is presented in the templates “PBKDF-1 (PKCS#5 2.0)” and “KDF Performance Comparison”.

Here, we show how easy it is to perform dictionary attacks, if passwords are just stored purely as hash values.

Task 1: The following password hashes are built with SHA-256. The passwords are English words, thus can be easily broken with a dictionary attack. Find them:

Hash1 = 5E 88 48 98 DA 28 04 71 51 D0 E5 6F 8D C6 29 27 73 60 3D 0D 6A AB BD D6 2A 11 EF 72 1D 15 42 D8

Hash2 = F4 C7 EC 93 81 10 87 E5 C3 DA 50 5C 08 0B E9 BA DA C8 B9 56 D6 2A A6 F1 3E 02 A5 6B BB BA EE 8A

Hash3 = 73 CD 1B 16 C4 FB 83 06 1A D1 8A 0B 29 B9 64 3A 68 D4 64 00 7A 4E 60 2F 84 A8 47 F5

Hash4 = 31 51 08 42 86 F5 95 11 CE 11 D4 FD 23 4B 64 85 01 25 14 58 7A 19 68 FA 55 AF FF 83 B0 5E 21 3E

Hint 1: Open the template “Dictionary Attack”. Here, enter the different hashes in the text input component “Test password – Hash-value (HEX)”. To speed up the search, minimize or remove the two text output components “Found index” and “Actual search password”.

Hint 2: If the password is not derived from a word in a dictionary the attacker has a much more difficult job – he/she has to perform a brute-force attack. On a modern PC around 10^8 hashes/sec can be calculated and checked.

Hint 3: This could be done even much faster with rainbow tables, if the attacker has enough memory.

Hint 4: If you buy services, insist that the according vendor uses modern password hashes on their webservers and in their applications. Use your power of demand (buyer power).

Task 12: Test the strength of different passwords

To do so, open the template “Check Password Strength” in CT2. Here, enter the different revealed passwords of Task 11 and give a comment about their strength values. Try to improve these passwords by extending their lengths, adding uppercase letters, numbers, and symbols or try to create a completely new secure password. Please don’t enter your real passwords since they are visible in clear – if you are not alone. CT2 reacts at once when changing the password. For the password strength, its length is much more important than different symbols!
Hint: Alternatively, you could use the plugin “Password Meter” on the website CrypTool-Online” (it’s menu entry can be found below the main menu “Highlights”; all calculations are done locally): https://www.cryptool.org/en/cto-highlights/passwordmeter
Appendix 1: Introduction to the CrypTool 2 Application

CrypTool 2 (CT2) consists of six main components:

- **Startcenter**
- **Wizard**
- **Workspace Manager**
- **Online Help**
- **Templates**
- **CrypCloud**

Here, the **Startcenter**, the **Wizard**, and the **Workspace Manager** are explained in more detail.

**a. Startcenter**

Every time you start the CT2 application, you will first see the **Startcenter**.

CT2 and the Startcenter consist of different areas marked with different colors in the above image.

The **blue area** ("ribbon bar") on the top of the image allows, either to create new workspaces or to open and save existing “CrypTool 2 workspaces” (shown later). Additionally, it allows to always go back to the Startcenter (yellow star icon on the right), to open the CT2 settings (hammer and screwdriver icon), to start the CrypCloud (cloud icon), to open the online help (question mark icon), and to start or stop the currently opened workspace (play and stop icons).
The **yellow area** contains a list of all open “tabs”. A tab is a kind of window containing the Startcenter, workspaces, etc. Tabs can be closed, if not needed anymore using the X icon of each tab. An arbitrary number of tabs can be opened but its amount is limited by the memory of the computer.

The **green area** of the Startcenter contains buttons to open all other components like the Wizard (magic wand), the Workspace Manager (2nd icon in the list), the online help (question mark icon), etc. Each button has a self-explaining text on its right side.

The **red area** of the Startcenter contains a list of all “templates” (more than 200) delivered with CT2. A template contains a specific cipher or a ready-to-run cryptanalytic scenario using the graphical programming language of CT2. The list of templates of the Startcenter can be filtered using keywords that can be entered in the search field.

Below the red area, you can find “Recently Opened Templates” showing a list of templates you opened in the past.

Finally, on the right side of the Startcenter you will see some “news”, showing the last changes we did on CT2 with respect to its source code.

**b. Wizard**

The Wizard is intended for users not familiar with using the graphical programming language of the Workspace Manager and for beginners. It guides you through the different topics of cryptology until you “reach what you want to do”, e.g. encrypt something or break something.

The Wizard can be started at two different places: First, by clicking in the top ribbon bar on the new icon and selecting “Wizard”.

Secondly, it can be started using the Startcenter and clicking here on the “Magic wand” button.
The Wizard consists of three main areas (here marked green, blue, and red).

In the **green area**, you can “select what you want to do”.

For example, you want to encrypt a text using the Caesar cipher: Then, first select “Encryption/Decryption” and click on “Next” in the **blue area**. Then, in the **red area**, the next page will appear.

**Remark:** **Navigation in the Wizard:** Instead of clicking on “Next” you may also double-click in the green area. The fastest way to navigate there is with the 4 arrow keyboard keys.
Then, the green area is updated with new options. The red area always contains some informational text based on the selections.

You repeat this step until you reach the “Caesar” cipher.

Here, you can enter the key and the text you want to encrypt. When you finally click “Next”, you will get the encrypted text.

In each final step in the Wizard, you may click on the Workspace Manager icon on the top right side (marked with orange above) of the Wizard to open a template in the Workspace Manager exactly corresponding to the cipher or cryptanalytic method you selected and currently used.
c. Workspace Manager

The **Workspace Manager** implements the graphical programming language of CT2. It allows to create arbitrary cascades of ciphers and cryptanalytic methods.

The Workspace Manager can be started at two different places: First, by clicking in the top ribbon bar on the new icon and selecting “Workspace”.

Secondly, it can be started using the Startcenter and clicking here on the “Workspace Manager” button.

A newly opened workspace of the Workspace Manager looks like this.

The **red area** in the middle is the actual workspace. It is used to create and present a visual program.
The **green area** on the left contains the list of components (components = cryptographic methods implemented in CT2). Each component can be put onto the workspace. To do so, just drag a component from the left side onto the workspace in the middle and drop it.

The **yellow area** is a logging window which contains messages generated by the components during the execution. It can be hidden by clicking the X icon in its upper left corner or via F11.

The **blue area** on the right side is the settings bar for a selected component. You can select any component in the workspace just by clicking on it. If a component is selected you can change its internal parameters here. The settings bar can be closed and opened with the gear-wheel button in the upper right corner (marked with a blue arrow in the picture above).

**Example: Building a Workflow for the Caesar Cipher**

Here we show how to build a workspace for the Caesar cipher from scratch with CT2. To do so, open the Workspace Manager as shown above.

Then, go to the list of components on the left side. Here, enter “caesar” in the search field (it is not case-sensitive).

Now, use the left mouse button to drag the “Caesar” component and put it onto the middle of the workspace.
After that, use the components list again to search for “text”.

Now, drag & drop a “Text Input” component to the left of the Caesar component and a “Text Output” component to the right of the Caesar component.

If you want to move them you can always drag a component. A minimized one can be dragged at each position within the icon (like the Caesar component in the picture). If it is “maximized” like the “Text Input” and “Text Output”, select the component by clicking on it. Then you can move the component using the upper gray corners or the lower left gray corner (marked red in the next picture).

To establish a workflow connect “Text Input” and “Text Output” with the Caesar component. For connections between components, CT2 offers connectors. Connectors are small colored rectangles on the left or right side of a component. You can drag & drop a line between output and input connectors. The color of a connector shows its data type. For example, a number connector is blue (.), a text connector is gray (.), and so on. As a rule of thumb: You can always connect connectors of the same color without any problems.
If you want to connect connectors with different colors, you may need converter components. Some data types can be converted implicitly. CT2 will show a hint if this happens.

If a connection is not possible CT2 shows an error.

If a connection is valid without any problems CT2 shows a green text.

Now, connect the three components, Caesar, “Text Input”, and “Text Output”, as shown in the next picture. Connecting is done by dragging a line with the mouse from the sender to the receiver.

Now, you have built your first graphical program.

Click on the text field of the “Text Input” component and enter some text.
Finally, click on the “Play” button in the top ribbon bar.

Now, CT2 executes your graphical program. The output should look like this.

Try to type into the “Text Input” while the graphical program is running. CT2 will update your ciphertext in the “Text Output” component at once.

To change your graphical program, you have to stop it using the “Stop” button in the top ribbon bar.

If you want to change for instance the key or any other setting of the Caesar cipher, select the Caesar component (just click on it), and use the toolbar on the right side of the workspace.

Here, with the Caesar component, you can change the key (shift number), the alphabet, etc.
d. Online help in CT2

For any component in CT2, there is some online help available. If you select a component on the workspace and click on the help icon, the according help file is shown.

**CrypTool 2 — Online Documentation**

Here, you can find a description of **all components delivered with CrypTool 2**.

- Order by alphabet
- Order by categories

Filter: ______________________ (197 matches)

**A**

- **Achterbahn**
  - Achterbahn is a stream cipher and was a phase 2 candidate in the eSTREAM Project

- **ADFGVX**
  - Cipher used in WW1, combining substitution and transposition

- **AES**
  - Advanced Encryption Standard (Rijndael)
Here is the beginning of the overview page of the templates in the CT2 online help:

Here, you can find a description of all pre-built templates delivered with CrypTool 2.

Order by alphabet  Order by categories

Filter:  (240 matches)

- Achterbahn Cipher
  Usage of the Achterbahn cipher

- ADFGVX Cipher
  Usage of the ADFGVX cipher

- ADFGVX Cipher dictionary attack
  Usage of the ADFGVX cipher

- AES (CBC) with PKCS#5 and IV
  Usage of the AES cipher in CBC mode with an initialization vector, where the session key is generated from a password using PKCS#5 and the ciphertext is encoded in base64

- AES (CBC) with PKCS#5 and IV, output as QR Code
  Usage of the AES cipher in CBC mode with an initialization vector, where the session key is generated from a password using PKCS#5 and the ciphertext is encoded in base64 and finally stored in a QR Code
Remark GUI 1: ** Quickly adapt the layout to your needs **

1) You can adapt the zoom level of the workspace using the left button in the top middle of the Workspace Manager (so with one click all elements optimally fill the given space).

2) Further hint for easy handling: Quickly adapt the whole CT2 GUI with the keyboard using F11 and F12 by fading-in or fading-out parts outside the actual workspace. So you can get the maximum space for the workspace within the CT2 window.

Remark GUI 2: ** Storage and persistence **

Each workspace can be stored as a file with the extension “cwm” (via the “Save” icon under the “Home” menu at the top of the CT2 main windows).

All given templates are also workspaces – predefined and delivered with CT2. So they are also stored in cwm files (see the directory “Templates” below the CT2 directory in your installation). Their specialty is that they are available in 2 or more languages at once.
Appendix 2: Task Overview

This document contains the following tasks:

- **Task 1**: Caesar Decryption
- **Task 2**: Caesar Encryption
- **Task 3**: Caesar Cryptanalysis – Using Character Frequencies
- **Task 4**: AES Decryption
- **Task 5**: AES Encryption
- **Task 6**: AES Cryptanalysis – Brute-Force (24 bit unknown)
- **Task 6a**: AES Cryptanalysis – Experience Different Search Times
- **Task 7**: RSA Decryption
- **Task 8**: RSA Encryption
- **Task 9**: RSA Cryptanalysis – Factorization of “Small” N
- **Task 10**: RSA Cryptanalysis – Attack on Common Prime Factors
- **Task 11**: Break Password Hashes – Preimage Attack Using a Dictionary
- **Task 12**: Test the Strength of Passwords
